

¹ Detecting skill level and mental templates in Late Acheulean
² biface morphology: Archaeological and experimental
³ insights

⁴ Cheng Liu* Nada Khreisheh† Dietrich Stout‡ Justin Pargeter§

⁵ **Abstract**

⁶ Despite the extensive literature focusing on Acheulean bifaces, especially the sources and
⁷ meaning of their morphological variability, many aspects of this topic remain elusive. Among
⁸ many factors identified to contribute to the considerable variation of biface morphology,
⁹ skill level and mental templates have been frequently cited. Here we present results from a
¹⁰ multidisciplinary study of Late Acheulean handaxe-making skill acquisition involving thirty
¹¹ naïve participants trained for minimally 0 hours (controlled group) and maximally 90 hours
¹² in Late Acheulean style handaxe production and three expert knappers. We compare their
¹³ handaxe to the Late Acheulean handaxe assemblage from Boxgrove, UK. Through the principal
¹⁴ component analysis of morphometric data derived from images, our study suggested that
¹⁵ both skill level and mental template have a relatively clear manifestation in different aspects
¹⁶ of biface morphology, where the former is related to cross-sectional thinning (PC1) while the
¹⁷ latter relates to handaxe elongation and pointedness (PC2). Moreover, we also evaluated the
¹⁸ effects of training using the data from a 90-hour long knapping skill acquisition experiment
¹⁹ and found that reaching the skill level of modern experts requires more training time than was
²⁰ permitted in this extensive and long-running training program. Our study demonstrated the
²¹ potential of experimental archaeology and digital photographs in revealing new insights from
²² old archaeological assemblages.

41 **1 Introduction**

42 The morphological variability of Acheulean bifaces has been one of the most well-studied and
 43 well-published topics in paleolithic archaeology (Key & Lycett, 2019; Petraglia & Korisettar, 1998;
 44 White, 1998). Despite the recurrent narrative emphasizing the homogeneity and longevity of
 45 biface assemblage on a global scale and the conservatism behind this phenomenon that evokes
 46 genetic explanations (Corbey et al., 2016; Corbey, 2020; Richerson & Boyd, 2005; Sterelny, 2004),
 47 many researchers have recognized the diversity within what has been deemed as a unified
 48 Acheulean “tradition” and tried to dissect the sources and meaning of this variation (Lycett &
 49 Gowlett, 2008; Nowell, 2002; Nowell & White, 2010; Sharon et al., 2011). More specifically, a
 50 complex suite of interconnecting factors have been identified to contribute to the great variation
 51 of biface morphology, including but not limited to raw materials (Eren et al., 2014; Lycett et
 52 al., 2016; Sharon, 2008), percussor properties (Shipton et al., 2009), function (Key et al., 2016;
 53 Key & Lycett, 2017; Kohn & Mithen, 1999; Machin et al., 2007; White & Foulds, 2018), reduction
 54 method/intensity (Shipton et al., 2009; Shipton & Clarkson, 2015), learning processes (Kempe
 55 et al., 2012; Lycett et al., 2016), skill level (Caruana & Herries, 2021; Herzlinger et al., 2017;
 56 Stout et al., 2014), mental template (García-Medrano et al., 2019; Hutchence & Scott, 2021).
 57 From this extensive list, skill level and mental template have been repeatedly mentioned and
 58 discussed in the now extensive corpus of biface studies, and Boxgrove handaxes have been
 59 one of the most studied assemblages from these two angles. Of particular attention here are
 60 the experimental works conducted by Stout et al. (2014) focusing on inferring high knapping

61 skill level and Garcia-Medrano et al. (2019) identifying the mental template of the Boxgrove
62 assemblage. Our paper combines these two perspectives and provides novel insights to the same
63 archaeological assemblage through comparing it with a unique experimental collection.

64 In its classical definition, the term mental template indicates that the “idea of the proper form
65 of an object exists in the mind of the maker, and when this idea is expressed in tangible form in
66 raw material, an artifact results” (Deetz, 1967: 45). This concept lies at the very foundation of the
67 cultural-historical approach in that the identification of archaeological cultures is based on the
68 existence of distinct mental templates in a given spatial-temporal framework. Early researchers,
69 whether explicitly or implicitly, often endorsed this conceptual framework and actively applies it
70 in the typological analysis of bifaces at the regional level (Roe, 1969; Wenban-Smith et al., 2000;
71 Wenban-Smith, 2004). Combined with the production of large flakes, the emergence of mental
72 templates (or “imposed form”) has been recognized as a major technological innovation of the
73 Acheulean compared with the Oldowan (Isaac, 1986). For a decade or so, this concept has been
74 less frequently used, since it was criticized for a) its normative and static assumption (Lyman &
75 O’Brien, 2004), b) ignorance of other competing factors such as raw material constraints (White,
76 1995), and c) the lack of rigorous studies of its corresponding cognitive processes. To avoid the
77 historical baggage associated with this controversial term, some researchers have also developed
78 alternative frameworks such as “design imperatives” purely derived from ergonomic principles,
79 which refers to a set of minimum features shared by all handaxes including glob-but, forward
80 extension, support for the working edge, lateral extension, thickness adjustment, and skewness
81 (Gowlett, 2006; Wynn & Gowlett, 2018).

82 Until very recently, several researchers have actively addressed the above-mentioned critiques
83 and reconceptualized the mental template in the study of biface morphology. Regarding the
84 normative and static assumptions, Hutchence and Scott (2021), for example, leveraged the
85 theory of “community of practice” (Wenger, 1998) to explain the stability of Boxgrove handaxe
86 design across multiple generations, especially how the social norms behind the consolidated
87 material expressions were developed and negotiated by individuals in a group who have a shared
88 history of learning. They further emphasized that emergent actions of individual knappers also
89 contribute greatly to the shape of Boxgrove handaxes but they were simultaneously constrained
90 by the imposition of social norms. This view also somewhat echoes the “individualized memic
91 construct” proposed by McNabb et al. (2004), which tries to provide a more balanced perspective

incorporating both individual agency and social learning. As for the critique towards confounding factors explaining morphological variability, raw material is often treated as a crucial variable to be controlled at the very beginning of a research design focusing on mental templates. This is best exemplified by an experimental study of García-Medrano et al. (2019), where they carefully chose experimental nodules mirroring those found in archaeological context in composition, size, and shape. In terms of the cognitive mechanisms behind mental templates, Ho and colleagues (2022) recently developed a series of navigation experiments demonstrating the externalization of the planning process to simple geometric representations instead of a complete representation of the given task, featuring both the efficiency and flexibility given the limited cognitive resources. Their experimental design has the potential to be transferred into a research setting aiming at directly testing the planning of knapping behaviors and elucidating how “mental templates” are constructed and perceived in brains. In short, when exercised with proper caution, the concept of mental template still has its value in our study of biface morphological variation, which can be further dissected into a series of shape variables corresponding to pointedness and elongation, among other things.

Following the reconceptualization of the mental template as a more flexible and interactive concept, one possible way of defining skill is the capacity for a knapper to realize mental templates using the resources available (Roux et al., 1995: 66). This version of conceptualization, particularly relevant when it comes to motor skills such as knapping, can be dismantled into two mutually dependent aspects, namely the intentional aspect (goal/strategic planning) and the operational aspect (means/motor execution) (Connolly & Dalgleish, 1989). It also roughly corresponds to the well-known dichotomy developed by French lithic analysts of “*connaissance*” (abstract knowledge) and “*savoir-faire*” (practical know-how) (Pelegrin, 1993). As Stout (2002: 694) noted, the acquisition of skill is deeply rooted in its social context, and it is not composed of “some rigid motor formula” but “how to act in order to solve a problem”. This ecological notion of skill somewhat mirrors Hutchence and Scott’s (2021) reconceptualization of the mental template in that they both refute the idea that technology is simply an internal program expressed by the mind and they prefer a dynamic approach emphasizing the interaction between perception and action. The manifestations of skill in materialized form display a great amount of variation, but ethnoarchaeological studies have repeatedly suggested that skills can be improved through practice as perceived by the local practitioners. It is thus possible to evaluate the skill levels reflected in knapping products (Roux et al., 1995; Stout, 2002). When contextual information is less readily

¹²⁴ available as in the Late Acheulean archaeological assemblages, how to properly operationalize
¹²⁵ and measure knapping skills has been a methodological issue receiving much attention among
¹²⁶ archaeologists (Bamforth & Finlay, 2008; Kolhatkar, 2022). In addition to measurements that can
¹²⁷ be almost applied in any lithic technological system such as raw materials, platform preparation,
¹²⁸ as well as hinges, in the context of biface technology, symmetry (Hodgson, 2015; Hutchence
¹²⁹ & Debackere, 2019) and cross-sectional thinning (Caruana, 2020; Pargeter et al., 2019; Stout et
¹³⁰ al., 2014) have been frequently quoted as reliable and distinctive indicators of the skill level as
¹³¹ supported by several experimental studies. These two features have also been commonly used as
¹³² standards for dividing Early Acheulean and Late Acheulean (Callahan, 1979; Clark, 2001; Schick &
¹³³ Toth, 1993).

¹³⁴ Drawing on these two lines of literature, we aim to explore the possibility of differentiating skill
¹³⁵ level and mental template and the interaction between the two through a comparative study of an
¹³⁶ archaeological biface assemblage known for its remarkable dexterity, a reference biface collection
¹³⁷ produced by modern knapping experts, and an experimental biface sample produced by modern
¹³⁸ novice knappers. Since the novice biface collection is generated from a 90-hour skill acquisition
¹³⁹ experiment, we also have the precious opportunity to introduce the diachronic dimension of
¹⁴⁰ training time and interrogate its impact on the variables of interest. As such, we propose the
¹⁴¹ following two interconnected research questions in this article: 1) Can skill level and mental
¹⁴² template be efficiently detected from biface morphometric data? 2) How does training affect
¹⁴³ novices' performance in these two aspects?

¹⁴⁴ 2 Materials and methods

¹⁴⁵ 2.1 Boxgrove biface collection

¹⁴⁶ The archaeological site of Boxgrove is located in the former Eartham quarry, Boxgrove, West
¹⁴⁷ Sussex, featuring a long sequence of Middle Pleistocene deposit (Pope et al., 2020; Roberts &
¹⁴⁸ Parfitt, 1998). This 500-ka-old site has documented exceedingly rich details of Lower Paleolithic
¹⁴⁹ hominins' subsistence behaviors (Smith, 2013, 2012) and their paleoenvironmental contexts
¹⁵⁰ (Holmes et al., 2010). In addition to the presence of one of the earliest hominin fossil (*Homo*
¹⁵¹ *heidelbergensis*, Hillson et al., 2010) and bone assemblages with anthropogenic modifications
¹⁵² in northern Europe (Bello et al., 2009), Boxgrove is mostly known for its large sample size of

153 Late Acheulean-style flint handaxes and the high dexterity reflected in their manufacture. As
154 such, it has received wide research attention in the past two decades regarding the relationships
155 between technology, cognition, and skills (García-Medrano et al., 2019; Iovita et al., 2017; Iovita
156 & McPherron, 2011; Shipton & Clarkson, 2015; Stout et al., 2014). To identify the morphological
157 manifestation of knappers' dexterity in our study, we selected a complete handaxe assemblage
158 (n=326) previously analyzed and reported in digital formats by Iovita and McPherron (Iovita &
159 McPherron, 2011), which is currently curated at the Franks House of the British Museum (Iovita et
160 al., 2017). The digital photographs are taken of each handaxe at a 90° angle, which was oriented
161 with the tip to the right of the photos, and the camera faces the most convex surface of the
162 handaxe (Iovita & McPherron, 2011).

163 **2.2 Experimental biface collection**

164 The biface experimental replicas used in this study comprised two sub-collection. The first
165 sub-collection includes 10 bifaces knapped by three expert knappers, including Bruce Bradley
166 (n=4), John Lord (n=3), and Dietrich Stout (n=3) (Stout et al., 2014). These handaxes were made
167 for previous research projects, which similarly aimed to approximate 'Late Acheulean' handaxes
168 explicitly comparable to the Boxgrove assemblage (Faisal et al., 2010; Stout et al., 2014; Stout et al.,
169 2011). The second sub-collection is produced from a 90-hour handaxe knapping skill acquisition
170 experiment (Bayani et al., 2021; Pargeter et al., 2020; Pargeter et al., 2019), where 30 adults with
171 no previous experience in knapping were recruited from Emory University and its surrounding
172 communities and requested to make 132 bifaces in total. Among these 30 adult participants, 17
173 have gone through multiple one-to-one or group training sessions that amounted to 89 hours
174 in maximum, while the remaining 13 were assigned to the controlled group, where no formal
175 training is given. As part of the preparation efforts, the experimental team spalled the Norfolk
176 flints acquired through Neolithics.com into flat blanks of similar size and shape for training and
177 assessments. The mechanical properties of these raw materials are comparable to the ones used
178 in Boxgrove in that they are both fine-grained and highly predictable in fracturing process.

179 In this experiment, all research participants participated in the initial assessment (assessment
180 1 in our data set) before formal training, where they each produced a handaxe after watching
181 three 15-minute videos of Late Acheulean style handaxes demonstrated by expert knappers and
182 examining four Late Acheulean style handaxe replicas from our expert sample. Training was

183 provided by verbal instruction and support from the second author, an experienced knapping
184 instructor ([Khreisheh et al., 2013](#)) with 10 years knapping practice and specific knowledge of Late
185 Acheulean technology including the Boxgrove handaxe assemblage. She was present at all training
186 sessions to provide help and instruction to participants. All training occurred under controlled
187 conditions at the outdoor knapping area of Emory's Paleolithic Technology Lab, with knapping
188 tools and raw materials provided. All participants were instructed in basic knapping techniques
189 including how to select appropriate percussors, initiate flaking on a nodule, maintain the correct
190 flaking gestures and angles, prepare flake platforms, visualize outcomes, deal with raw material
191 imperfections, and correct mistakes. Handaxe-specific instruction included establishment and
192 maintenance of a bifacial plane, cross-sectional thinning, and overall shaping. The training
193 emphasized both aspects of handaxe making technical skill (the importance of producing thin
194 pieces with centered edges) as well as mental template related markers (symmetrical edges).

195 Subsequently, the 17 participants in the experimental group were assessed after every ten hours
196 of the cumulative learning period, where each of them was requested to produce a handaxe for
197 expert knapper's (N. Khreisheh) review, leading to the compilation of a data set composing 9
198 assessments in total. It should be also noted that 6 out of 17 participants dropped out of the
199 research before the final assessment due to personal reasons. To detect the effect of training
200 on skill level and mental template, we reorganized our assessment classification scheme and
201 combined it into three broader categories, namely pre-training (assessment 1), early training
202 (assessment 2-5), and late training (assessment 6-9), which helps increase the sample size of
203 the measured intervals. A more detailed experimental protocol can be assessed in one of our
204 published papers ([Pargeter et al., 2019](#)).

205 2.3 Lithic analysis

206 To better understand the morphological variation of Boxgrove biface collection, we adopted a
207 standardized analytical procedure to extract the morphometric information from 752 photos of
208 the studied samples ([Iovita & McPherron, 2011](#)), which include both the front and lateral views
209 of a given specimen. First, we used Adobe Photoshop to conduct a batch transformation of the
210 samples' pixel scale into a real-world measurement scale based on the fixed photographic setting.
211 This is then followed by the batch conversion of color photographs to a black-and-white binary
212 format. Subsequently, we cropped the silhouettes of bifaces one by one using the Quick Selection

213 Tool in Adobe Photoshop. The metric measurements were conducted in ImageJ (Rueden et al.,
 214 2017), where we employed a custom ImageJ script (Pargeter et al., 2019) to measure the maximum
 215 length, width, and thickness of a given silhouette. The width and thickness measurements are
 216 taken at 10% increments of length starting at the tip of each biface (Figure 1), which eventually
 217 leads to 19 morphometric variables in total (1 length measurement, 9 width measurements,
 218 and 9 thickness measurements). Finally, we calculated the geometric means of all 19 linear
 219 measurements to create a scale-free data set that preserves the individual morphological variation
 220 at the same time (Lycett et al., 2006). This allometric scaling procedure controls for size variation
 221 which may come from initial blanks and/or reduction intensity (shaping/resharpening). Notably,
 222 Shipton and Clarkson (2015) previously found that reduction intensity does not have a strong
 223 impact on the shape of handaxes. The same procedure was also applied to the morphometric
 224 analyses of the experimental biface collection, which was partially published in Pargeter et al.
 225 (2019).

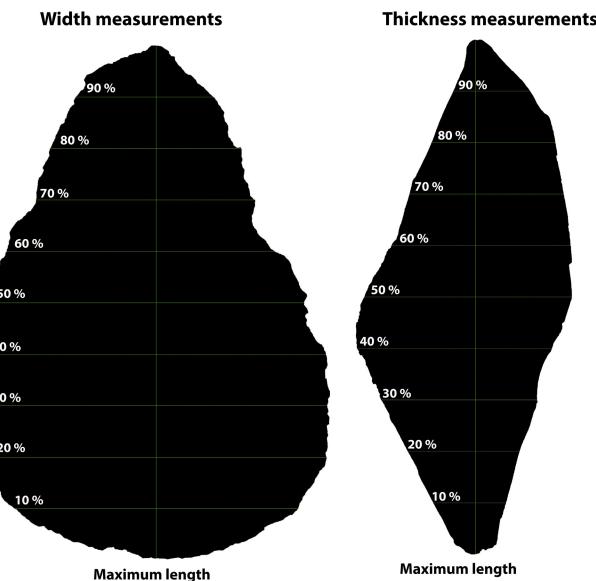

Figure 1: A visual demonstration of the biface measurement protocol using Image J (after Pargeter et al. 2019: Figure 5).

226 2.4 Statistical analyses

227 Given the number of variables involved in this study, we used principal component analysis (PCA)
 228 to reduce the dimension and identify the possible patterns in this morphometric data set, which
 229 is one of the most used techniques in similar studies (García-Medrano, Maldonado-Garrido,
 230 et al., 2020; García-Medrano, Ashton, et al., 2020; Herzlinger et al., 2017; Iovita & McPherron,
 231 2011; Shipton & Clarkson, 2015; Stout et al., 2014). To detect the effect of training on novices'

232 performance as compared with archaeological samples and biface made by experts, we also
233 compare the corresponding metrics built on PCA across different training periods and across
234 all groups using the Games-Howell nonparametric post-hoc test, which does not rely on the
235 assumptions of equal sample sizes and equal variance. This study adheres to the principles of
236 reproducibility and data transparency of archaeological research by depositing all the codes and
237 data sets involved in an open-access online repository ([Marwick, 2017](#)), which can be accessed
238 through the author's Github (<https://github.com/Raylc/PaST-pilot>).

239 3 Results

240 3.1 Principal component analysis

241 Our analysis suggested that the first two components already explain 77.2% of the variation for the
242 entire morphometric data set composed of 19 variables (**Figure 2**), which is a rather reasonable
243 explained variance ratio to avoid overfitting. Variable loadings (**Table 1**) indicate that the first
244 principal component (PC1) captures overall cross-sectional thickness. It is positively correlated
245 with all thickness measurements while negatively correlated with all other measurements. A
246 higher PC1 value thus indicates a thicker biface, and vice versa. The second principal component
247 (PC2) tracks elongation and pointedness, as indicated by a positive covariance of maximum
248 length and bottom width/thickness. As PC2 increases, a biface will be relatively longer and more
249 convergent from the broad base to the tip.. Thus, PC1 corresponds to cross-sectional thinning
250 and PC2 to overall shape variation.

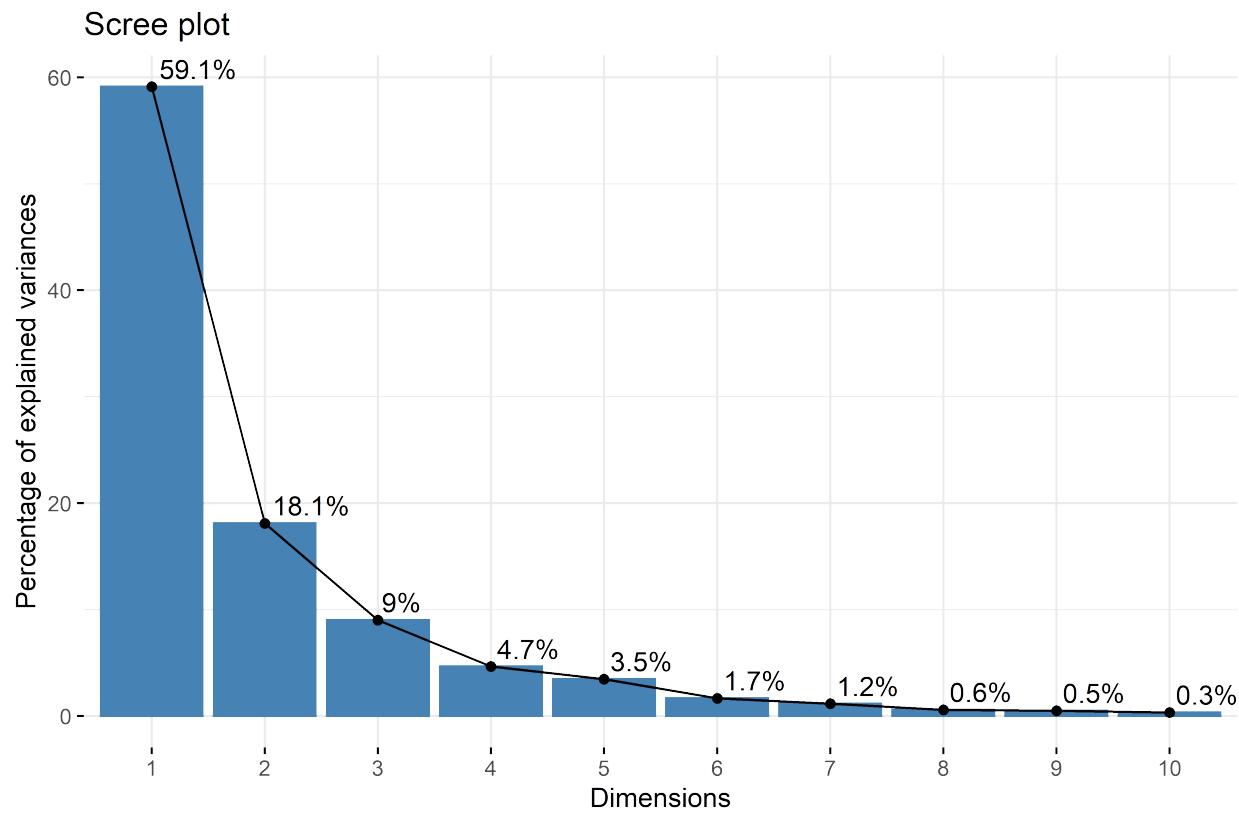

Figure 2: A scree plot showing the percentage of explained variances of the first 10 principal components.

251 A closer look at the principal component scatter plot ([Figure 3](#)) yields the clustering of different
 252 groups of bifaces. The majority of Boxgrove bifaces occupy an area featuring negative values of
 253 both PC1 and PC2. The expert group is similar to the Boxgrove group in PC1, while the former has
 254 a relatively higher PC2 value than the latter on average. The group of novice displays the highest
 255 level of variability, however, it is rather pronounced that most bifaces made by novices have a
 256 positive PC1 value that is different from both the groups of Boxgrove and experts.

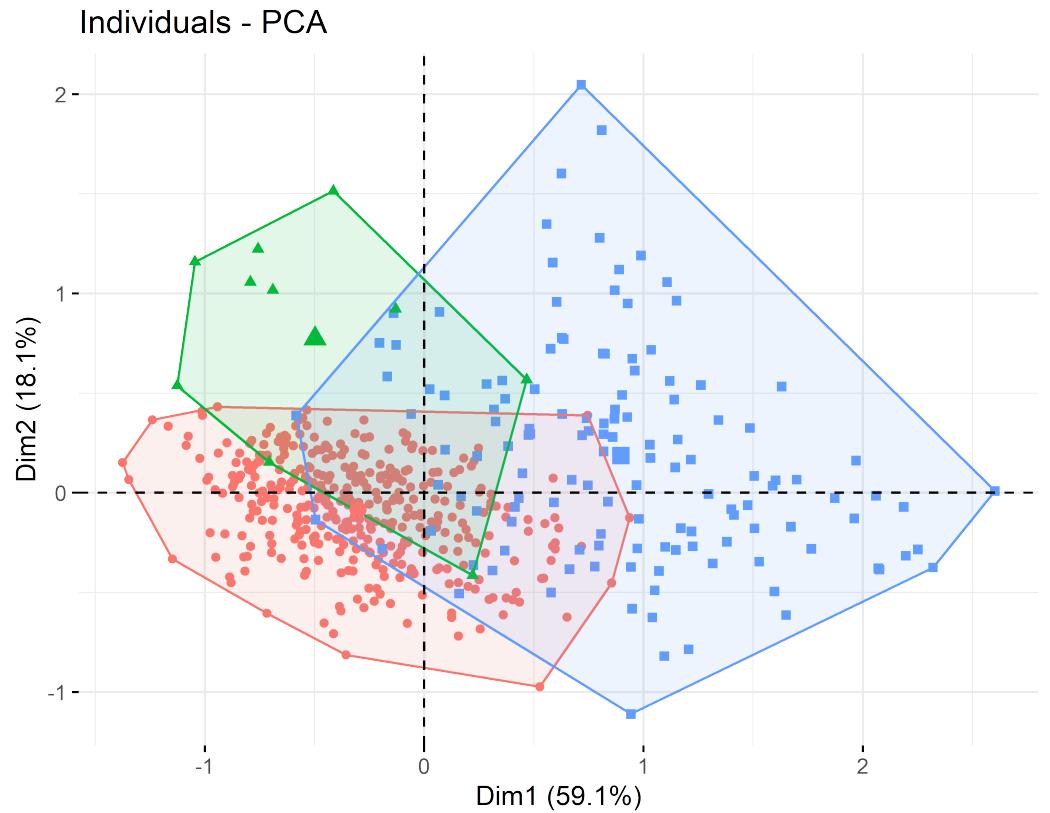

Figure 3: A principal component scatter plot of bifaces from the groups of Boxgrove (red, n=326), expert (green, n=10), and novice (blue, n=132).

257 In addition, visual inspection of the principle component scatter plot (Fig.) suggested that
 258 PC1 and PC2 might be negatively correlated within the Boxgrove and Expert groups. To test
 259 this, we conducted a series of exploratory plotting and statistical analyses of the PC values of
 260 three groups analyzed in our analysis (**Figure 4**). Across all three groups, a negative correlation has
 261 been displayed between the PC1 and PC2 values, although this trend is not statistically significant
 262 ($r=-0.41$, $p= 0.24$) in the expert group, probably because of its small sample size.

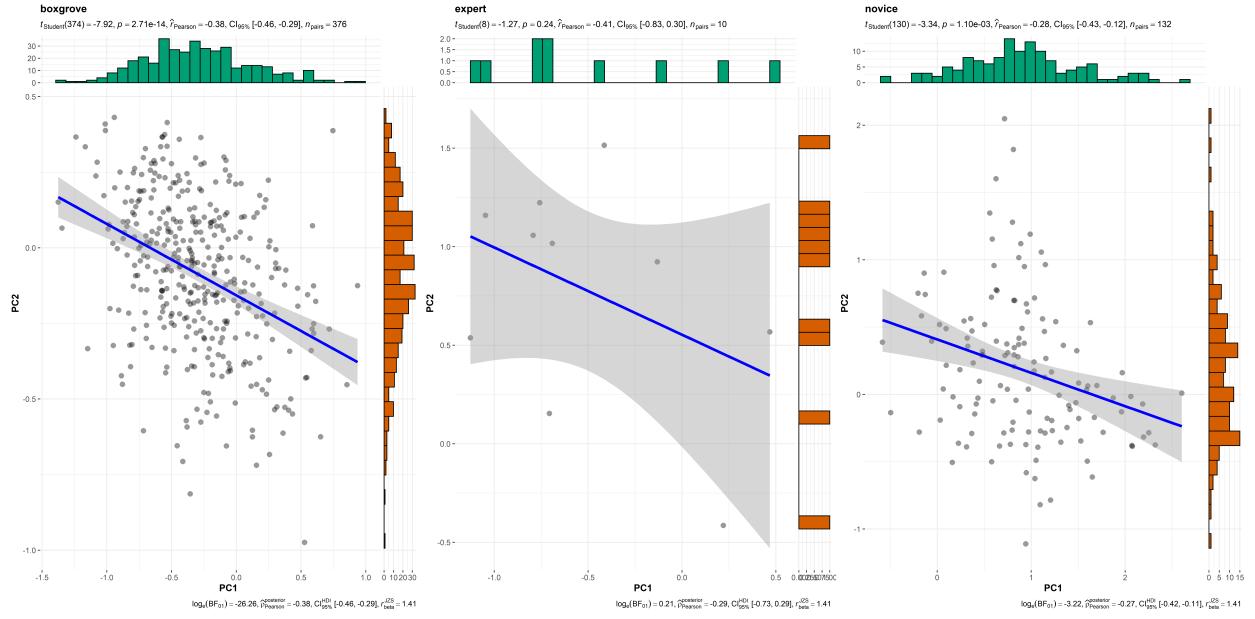

Figure 4: A scatter plot showing the correlation between PC1 and PC2 respectively in the groups of Boxgrove (left, $n=326$), expert (middle, $n=10$), and novice (right, $n=132$).

263 3.2 Effects of training

264 We extracted the PC1 and PC2 values of individual bifaces and compared them between different
 265 groups. More specifically, the novice group was divided into three sub-groups based on their
 266 training stages as specified in the method section. As such, we found that for PC1 values (**Figure**
 267 **5**), the only two group comparisons that are **not** statistically significant are the one between
 268 Boxgrove and Expert ($t = -1.65, p > 0.05$) and the one between Early training and Late training
 269 stages ($t = -0.649, p > 0.05$), which at least partially confirms our visual observation of the
 270 general PCA scatter plot. Likewise, for PC2 values (**Figure 6**), the group comparison between
 271 the Early training and Late stages again is **not** statistically significant ($t = 0.333, p > 0.05$). An
 272 unexpected result is that the mean PC2 value difference between the Pre-training group and
 273 Boxgrove is also **not** statistically significant ($t = -0.818, p > 0.05$).

A between-group comparison of PC1 values

$$F_{\text{Welch}}(4, 44.97) = 119.31, p = 2.45\text{e-}23, \widehat{\omega_p^2} = 0.90, \text{CI}_{95\%} [0.86, 1.00], n_{\text{obs}} = 518$$

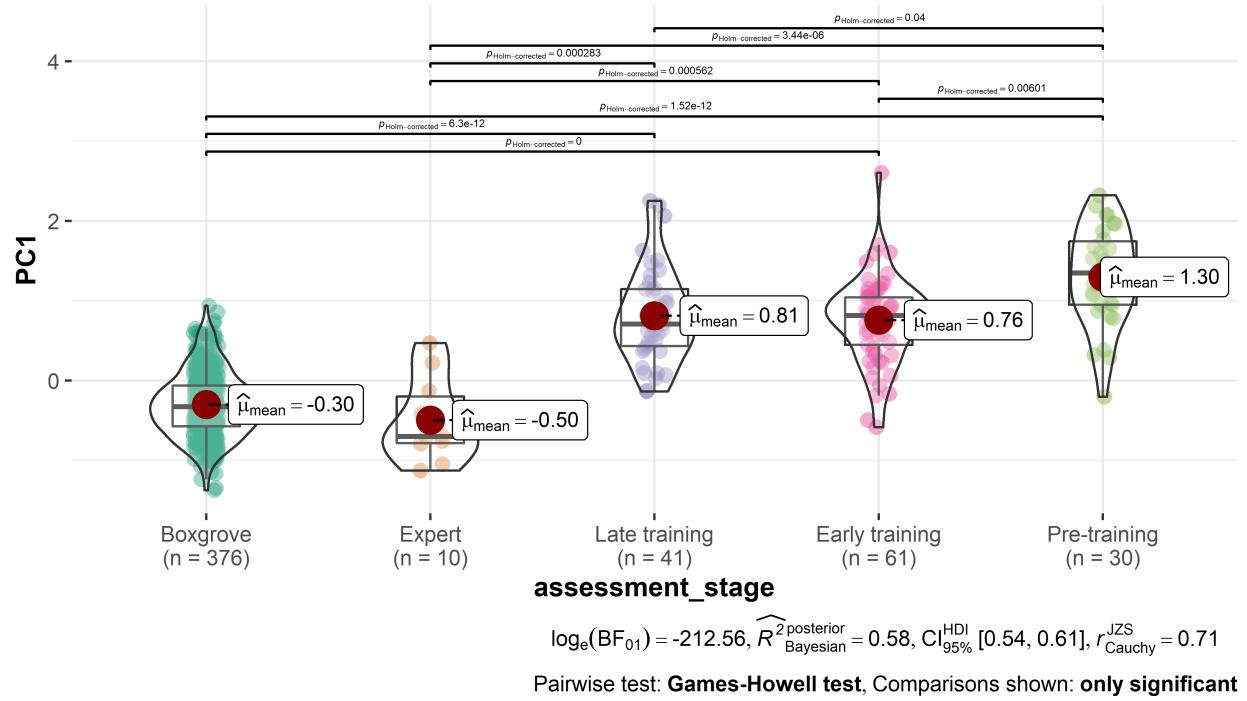

Figure 5: A between-group comparison of PC1 values.

A between-group comparison of PC2 values

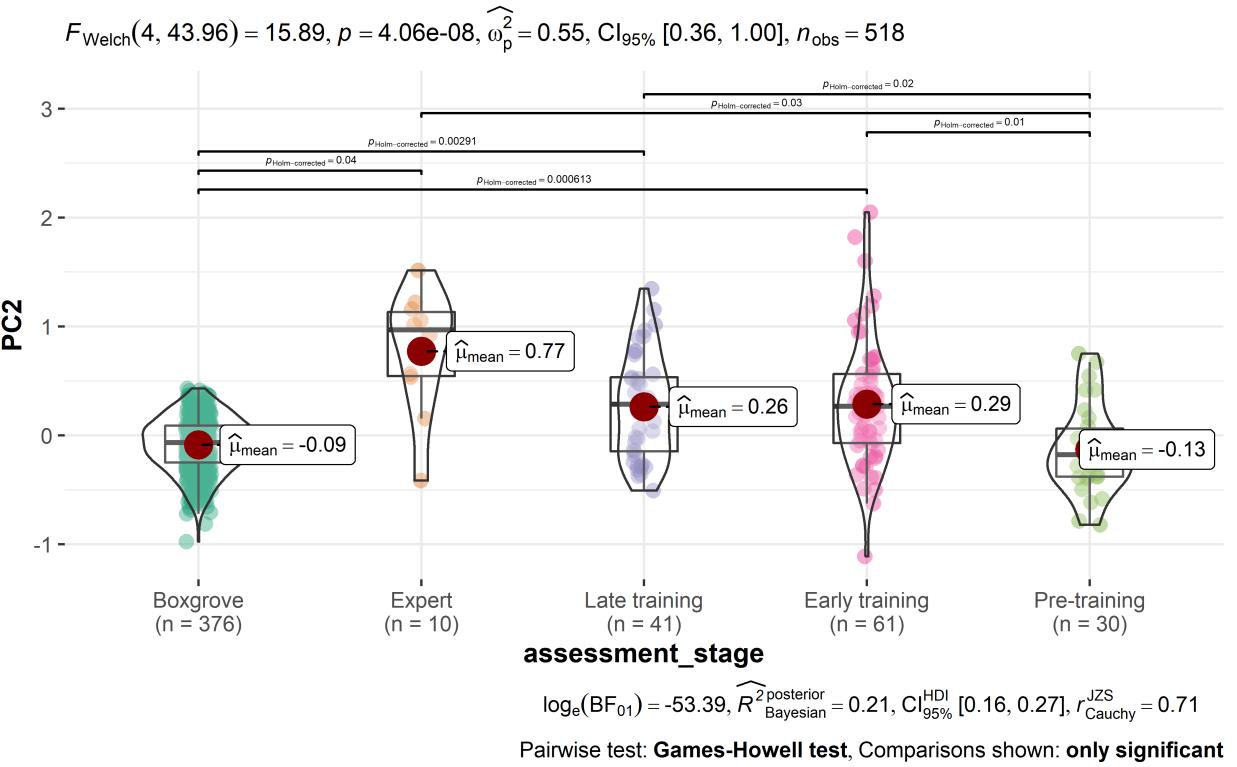

Figure 6: A between-group comparison of PC2 values.

274 4 Discussion

275 Our study suggested that both skill level and mental template have a relatively clear manifestation
 276 in different aspects of biface morphology, where the former is related to cross-sectional thinning
 277 (PC1) while the latter relates to handaxe elongation and pointedness (PC2). Moreover, we also
 278 evaluated the effects of training using the data from a 90-hour long knapping skill acquisition
 279 experiment and found that reaching the skill level of modern experts requires more training
 280 time than was permitted in this extensive and long-running training program. In accordance
 281 with the existing literature on biface knapping skill (Callahan, 1979; Caruana, 2020; Stout et al.,
 282 2014), the results of PCA suggested that PC1 (cross-sectional thinning) is a robust indicator of
 283 skill level as it is a common feature shared by modern expert knapper and Boxgrove knappers.
 284 Thinning is regarded as a technique requiring a high knapping skill level because it requires
 285 one to carefully detach flakes in an invasive manner while not breaking the biface into several
 286 pieces, serving the purpose of achieving the desired convexity and/or volume. This procedure

287 involves precise control of striking forces, strategic choice of platform external angle, and attentive
288 preparation of bifacial intersection plane, all of which were part of our experimental training
289 program ([Callahan, 1979](#); [Caruana, 2022](#); [Pargeter et al., 2020](#); [Shipton et al., 2013](#); [Stout et al.,](#)
290 [2014](#)). Experimental studies have also shown that the thinning stage of biface produce often
291 involves the use of soft hammers, which is also supported by indirect archaeological evidence
292 of flake attributes from Boxgrove ([Roberts & Parfitt, 1998](#): 384-394; [Roberts & Pope, 2009](#)). This
293 also reflects the majority of samples in both our expert and novice experimental assemblages. In
294 the skill acquisition experiments, novice knappers have been explicitly taught to switch to the
295 soft hammer for thinning purposes, but some of them did not follow the instruction during the
296 assessment. On the other hand, it has also been shown that hard hammers can also be used to
297 achieve similar thinning results ([Bradley & Sampson, 1986](#); [Pelcin, 1997](#)), corresponding to the
298 cases of replicas produced by Bruce Bradley.

299 Given the dissimilarity of PC2 (elongation and pointedness) values between archaeological and
300 experimental samples and its similarity among modern knappers, we argue that this dimension
301 reflects different mental templates, where the Boxgrove assemblage displays an ovate shape
302 featuring a wider tip while the experimental assemblages are characterized by a more pointed
303 shape with a longer central axis. Our results regarding the ovate plan morphology of the Boxgrove
304 assemblage generally supports what have been reported by Shipton and White ([2020](#)) as well
305 as Garcia-Medrano et al. ([2019](#)). This pattern may reflect a divergence of group-level aesthetic
306 choices as expected under the theoretical framework of the communities of practice ([Wenger,](#)
307 [1998](#)) as advocated by Hutchence and Scott in biface analysis([2021](#)). The most common form of
308 learning in the experiment occurred in the group condition, where the instructor, as the compe-
309 tent group member, directed the joint enterprise through actively teaching multiple novices at the
310 same time. Meanwhile, novices had the chance to also communicate and learn from their peers,
311 producing a shared repertoire of artifacts and actions. Unfortunately, the biface data from the
312 instructor (N. Khreisheh) are unavailable, but it should be noted that the instructor has learned
313 how to knap and how to teach knapping from one of our expert knapper (Bruce Bradley). This
314 cascading effect of social learning might explain why there is a shared mental template between
315 the expert group and the novice group after training.

316 The negative correlation between the PC1 and PC2 values revealed a hidden structural constraint
317 regarding the relationship between cross-sectional thinning and the imposed form. Our results

318 (Fig.) suggested thinner handaxes (low PC1 value) are generally more pointed/less ovate (high
319 PC2 value). In the thinning phase of handaxe making, a knapper must strike flakes that travel
320 more than one half way across the surface. Consequently, it would be easier to perform thinning
321 if the plan shape of a handaxe is narrower and more pointed. It is possible that such constraints
322 help to explain the convergence of our novice knappers on similar shapes to those preferred by
323 modern expert knappers, however, this clearly does not explain the design target at Boxgrove.
324 Given the ovate forms of the Boxgrove assemblage, it thus requires a high skill level to overcome
325 this structural constraint to produce thin yet wide handaxes as demonstrated by the Boxgrove
326 knappers. This also provides an alternative explanation to the social transmission of form for the
327 experimental convergence of on pointed forms. In this comparative context, it would only be
328 the Boxgrove assemblage that provided evidence of social conformity on a more difficult target
329 shape.

330 In terms of our second research question, this study shows that training does have an immediate
331 intervention effect (pre-training vs. post-training) in both PC1 (skill level) and PC2 (mental tem-
332 plate). Nonetheless, once the training has been initiated, its effects across different assessments
333 on both dimensions are rather inconspicuous. This finding corroborates what has been suggested
334 in Pargeter et al. (2019) that 90 hours of training for handaxe making is still not enough for
335 novices to reach the skill level as reflected in expert knappers, even considering the massive social
336 support involved in the experiment set up including the direct and deliberate pedagogy and
337 the simplified raw material procurement and preparation procedures. This follow-up project
338 further adds the samples produced by the Late Acheulean toolmaker as a new benchmark to
339 deepen our understanding of this issue. It is noteworthy how constrained the range of Boxgrove
340 assemblage morphological variation is as measured by both PC1 and PC2 even when compared
341 with the modern expert group (**Figure 3**), especially given the fact that it has the largest sample
342 size among all studied groups. Some potential explanations for this phenomenon include 1)
343 the strong idiosyncrasy of individual expert knappers shaped by their own unique learning and
344 practice experience; and/or 2) the present day-skill shortage of our expert knapper as compared
345 with Boxgrove knappers despite their multiple years of knapping practice ([Milks, 2019](#)).

346 The pre-training group is similar to the Boxgrove group in PC2 because these novices lack the
347 ability to effectively reduce the nodules, which are typically flat pre-prepared cortical flakes, to
348 the desired form (**Figure 7**). If the given nodules already possess an oval morphology like those

349 presented in the Boxgrove assemblage, it is likely the form of end products knapped by novices
350 in the pre-training group will remain roughly unchanged. This explanation is also supported
351 by the comparison of average delta weight, defined as the difference between the weight of
352 handaxe and the weight of nodule, among four groups, where the pre-training group displays
353 the lowest value (**Figure 8**). It might be worth noting that the expert group is highly variable
354 probably due to raw material starting size/shape. Experts generally try to achieve handaxe
355 forms while removing as little mass as possible (i.e. making as big a handaxe as possible from
356 the nodule). On the other hand, the refitting analyses of the Boxgrove handaxe assemblage
357 have suggested that the nodules exploited by knappers inhabiting this site are somewhat bulky
358 and amorphous (Roberts & Parfitt, 1998: 339, 360). These characteristics have been clearly
359 displayed in a recent attempt of slow-motion refitting of a handaxe specimen from Boxgrove
360 GTP17 (<https://www.youtube.com/watch?v=iS58MUJ1ZEo>). As such, behind the resemblance of
361 the pre-training group and the Boxgrove assemblage in PC2 are two types of mechanisms that
362 are fundamentally different from each other, where the latter group exhibits a complex suite of
363 cognitive and motor execution processes to transform the shapeless raw materials to a delicate
364 end product in a given shape.

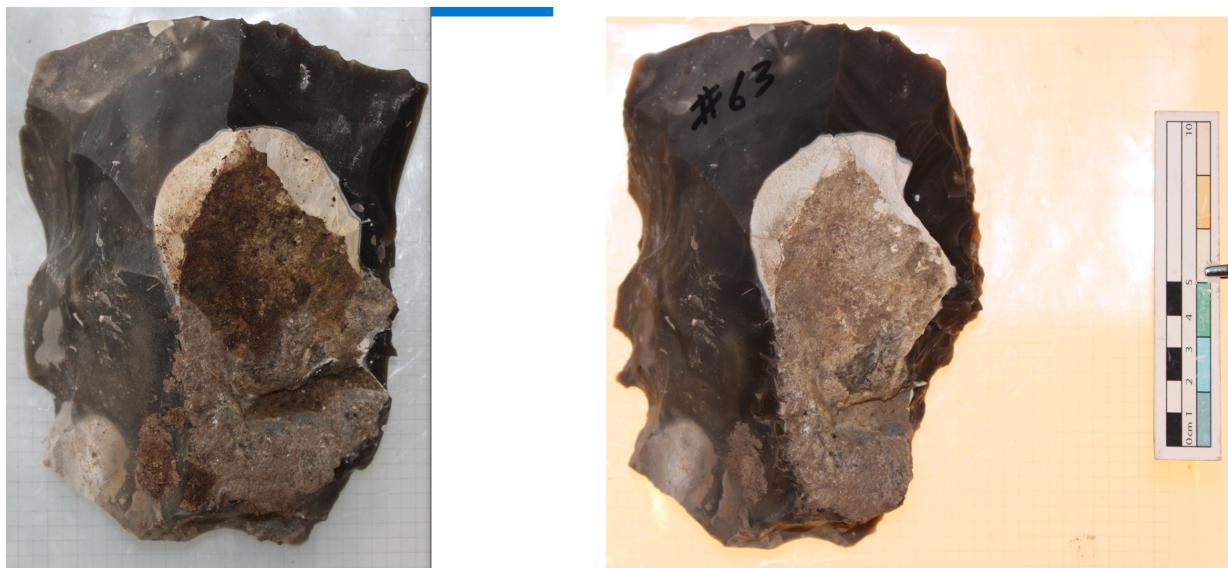

Figure 7: Core 63 before (left) and after knapping(right), showing the minimal morphological change during the process

A between-group comparison of delta weight

$$F_{\text{Welch}}(3, 34.01) = 10.52, p = 4.81e-05, \widehat{\omega_p^2} = 0.43, \text{CI}_{95\%} [0.19, 1.00], n_{\text{obs}} = 142$$

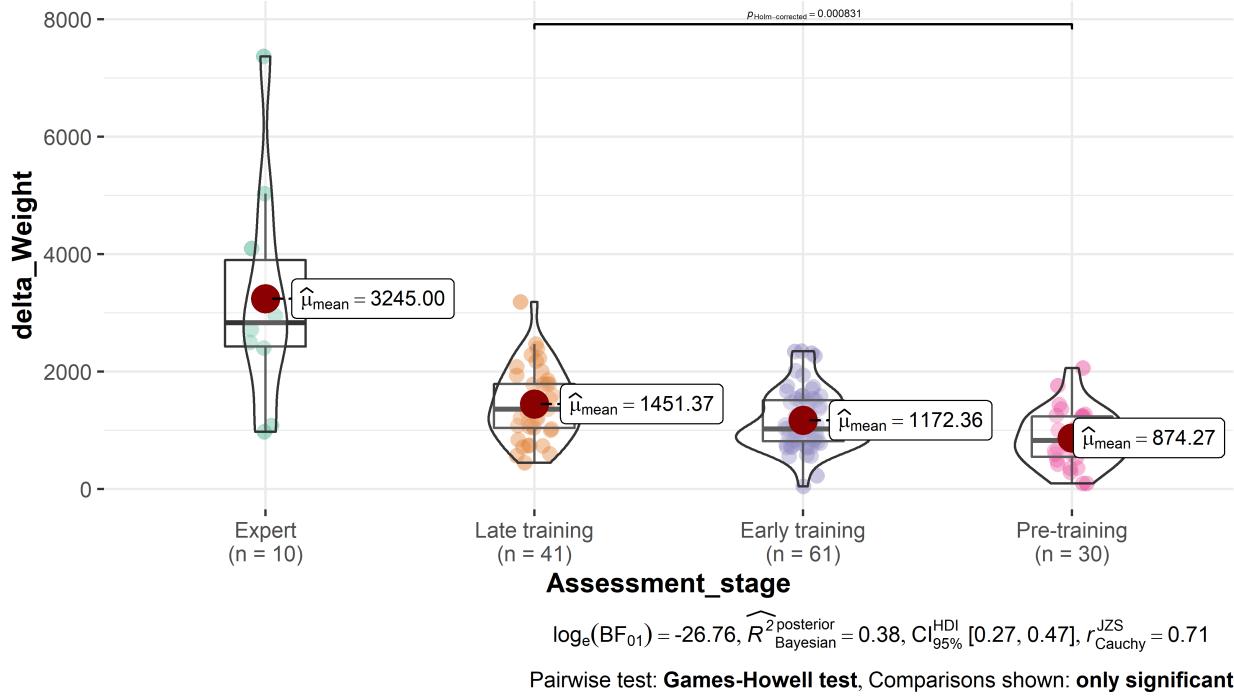

Figure 8: A comparison of the delta weight between the pre-training, early training, late training, and the expert group.

365 Another contribution that we would like to highlight here is that this research project demon-
 366 strates the potential of reusing old archaeological data in digital format to address novel research
 367 questions. In this paper, the main source of archaeological data is a collection of photos produced
 368 and curated by one of our co-authors (R. Iovita) more than 10 years ago, and the morphological
 369 variation data of the experimental collection are also derived from photographs instead of remeas-
 370 urements of the original artifacts. Given the irreversible nature of archaeological excavations,
 371 digitized data, be it text, pictures, or videos, often become the sole evidence that is available for
 372 certain research questions. Yet, it has been widely acknowledged that the reuse of archaeological
 373 data has not received enough attention among researchers in our discipline (Faniel et al., 2018;
 374 Huggett, 2018; Moody et al., 2021). Among many reasons preventing archaeologists from reusing
 375 published and digitized data (Sobotkova, 2018), the lack of a standardized practice of and motiva-
 376 tion for data sharing is a prominent one (Marwick & Birch, 2018). As stated in the method section,
 377 we addressed this issue by sharing the raw data and the code for generating the derived data on
 378 an open-access repository. Another major and legitimate concern of archaeological data reuse is

379 their quality. In terms of this aspect, we do acknowledge the limitations of relying on photos when
380 it comes to the more detailed technological analysis of stone artifacts, however, our paper shows
381 that finding the appropriate research questions given the data available is key to revealing new
382 novel insights into the studied topic. Moreover, we believe that this type of research has a strong
383 contemporary relevance due to the continued influence of the COVID-19 on fieldwork-related
384 travel and direct access to archaeological artifacts (Balandier et al., 2022; Ogundiran, 2021).

385 5 Conclusions

386 Regarding the two research questions we proposed in the beginning, our case study suggested
387 that 1) we can delineate the effects of skill level and mental template through the multivariate
388 analysis of morphometric data, where the former is associated with cross-sectional thinning
389 while the latter is reflected in elongation and pointedness; 2) Training has an immediate effect of
390 convergence on shared design targets, but 90 hours of training is still not enough for novice to
391 reach the level of expertise as reflected in modern experienced knappers, let alone the Boxgrove
392 tool makers. At a larger theoretical level it questions the distinction between social learning of
393 design targets vs. individual learning of the skills needed to achieve them. To illustrate, a thin cross
394 section could be part of a mental template or design target and was explicitly instructed by our
395 expert instructor to novices, but novices cannot fully understand nor achieve this technological
396 goal due to the constraint of skill level, making it a robust indicator of the latter. In the future,
397 more robust experimental studies are needed to deepen our understanding of the relationship
398 between skill acquisition and the morphological variability of bifaces as well as their implications
399 for the biological and cultural evolution of the hominin lineages.
